Oasis: supplementary repository results

Paper ID 1352. Frozen completed-archive snapshot, 9 November 2026.

This supplement enumerates all 62 completed catalog 3 repository attempts, including unavailable mutation scores. The primary study contains 47 scored repositories; 39 pass every selected baseline and eight retain blocked scopes. Fifteen completed attempts yield no scored cases. N.a. is not a zero mutation score. The 95-entry admission/disposition ledger and full case/command CSVs accompany the editable evidence package. One in-progress repository, three failed preparations and 29 unstarted repositories have no primary mutation contribution at this snapshot. Historical catalog 2 evidence and the 123-case matched study remain separate.

Table 1: All 62 completed catalog 3 repository attempts. B: passing/blocked selected baselines; N: scored cases. No-score entries are n.a., not zero adequacy.

Historical adaptation accounting

The original 23-source cohort includes research execution adaptations. This ledger does not classify a repository as unchanged merely because an applied change ledger is unavailable. Catalog 3 archive receipts record no assertion changes in that phase for all 62 completed attempts: 15 historically adapted sources, 20 first additions and 27 reserves. That per-phase field does not establish that inherited assertions or fixtures were pristine upstream.

The retained final source manifest, selected hash-matched scanner-source files and explicit adapter recipes support the bounded accounting below. A recipe-only record describes intended conditional preparation, not proof of every applied branch. Complete per-repository/category counts and causal attribution to scored cases are unavailable without the historical applied ledgers. The machine-readable `polish-evidence/historical-adaptation-ledger.csv` lists all 23 historical repositories, with unknown entries explicit.

Table 2: Bounded historical adaptation evidence. "Verified final" means final bytes matched the frozen source manifest; it is not a complete original-to-adapted patch audit.

Repository	Evidence level	Supported preparation evidence
`aws-platform-starter`	Recipe only	Environment identity and subnet fixture corrections are described; applied totals are unknown.
`conf-data-processing-architecture-reference`	Verified final and recipes	A research smoke plan with synthetic inputs and a mocked Google provider has no assertions. Provider-requirement files are manifested. Other provider/path/fixture corrections are recipe evidence, not a complete applied ledger.
`genai-idp-terraform`	Verified final and recipes	A feature-condition source repair and an added service fixture are present in final source copies and have named recipe anchors. Other adaptation totals are unknown.
`platform-design`	Verified final and recipes	Final VPC tests contain repaired output/schema assertion expressions and a plan-known name-prefix check. A generated provider requirement is present. These are not proof that every repair preserved the upstream oracle.
`psoxy`	Recipe only	Synthetic prebuilt bundle/hash inputs and an artifacts-bucket fixture are described; applied file/category totals are unknown.
`server-terraform`	Verified final and recipe	A research Google-beta provider requirement is present and matches the source manifest; other adaptation totals are unknown.
`terraform-duploclou d-components`	Recipe only	Public-value synthetic parser fixtures, engine constraints and mock/compatibility corrections are described. Credential-bearing files were not inspected. Applied totals are unknown.

For the remaining 16 historical repositories, repository-specific applied ledgers were not available in the inspected retained metadata: `aws-terraform-infrastructure`, `cloud-native-deployment-platform`, `eks-vulnerable-infra`, `platform-tools`, `serverless-architecture-patterns`, `terraform-aws-compliance`, `terraform-aws-lb`, `terraform-aws-oidc-github`, `terraform-aws-security-group`, `terraform-aws-sonarqube`, `terraform-aws-static-site`, `terraform-aws-vpc`, `terraform-datadog-users`, `terraform-mongodbatlas-project`, `terraform-postgres-config-dbs-users-roles` and `tofu-modules`. Their adaptation categories remain unknown; generic adapters were conditional, so absence of a research-named file is not evidence of no change.

Assertion repairs and smoke-only scopes. Retained historical recipes included removal of assertions whose complete condition was constant true or false, leaving their runs as smoke tests. Remaining assertion counts cannot recover how many were removed. In the historical 276-case expanded study, 17 passing zero-assertion scopes yielded 21 scored survivors: all 21 came from 12 `platform-design` scopes. The other zero-assertion scopes were one conf-data, one DuploCloud and three `tofu-modules` scopes, contributing no scored cases. These are historical counts, not a catalog 3 sensitivity analysis; the specifically added conf-data smoke plan is not the source of those 21 survivors.

Native evidence for the Equinor worked example

The case is `MUT-CFG-001@variables.tf:32:d7627b5073ef`, upstream revision `0f92db17bd6a69ac997333fa7eedae877b1aa473`. The archive SHA-256 is `e463b285812dfbd0f32d3666dd26c4d6c76d26326a43efb2ae2914b1cb13c964`. Selected source/test/log members were read directly from that small completed archive and verified against its source snapshot and results manifest; no native command was rerun.

The existing `tests/soft-delete.tftest.hcl` uses a mocked Azure provider. Its plan run `soft_delete_defaults` omits `purge_protection_enabled`; `variables.tf:32` supplies the default and `main.tf` forwards it into `azurerm_key_vault.this`. The mutant is valid but the retained native diagnostic at test line 26 reports the planned purge-protection value as false against the expected true. Unmutated summary: 25 passed, no failures. Mutant summary: 24 passed, one assertion failure, no runtime errors. Explicit-true and explicit-false runs passed; the resolver conservatively marked them unresolved because other supplied inputs were expressions. At least one active route was sufficient for the mutant to be tested.

Processed evidence is retained in `polish-evidence/worked-example-evidence.json`. It includes the exact diagnostic, summaries, source and member hashes, selected command, runtime/provider versions and binding records. This demonstrates sensitivity to an existing planned-resource contract, not a live cloud incident or representative real-fault coupling. Evidence-access arrangements and full native archives remain separate from this processed supplement.
